

FEATURES

- Lowest auto-zero amplifier noise
- Low offset voltage: 1 μV
- Input offset drift: 0.002 $\mu\text{V}/^\circ\text{C}$
- Rail-to-rail input and output swing
- 5 V single-supply operation
- High gain, CMRR, and PSRR: 120 dB
- Very low input bias current: 100 pA max
- Low supply current: 1.0 mA
- Overload recovery time: 10 μs
- No external components required

APPLICATIONS

- Automotive sensors
- Pressure and position sensors
- Strain gage amplifiers
- Medical instrumentation
- Thermocouple amplifiers
- Precision current sensing
- Photodiode amplifier

GENERAL DESCRIPTION

This new breed of amplifier has ultralow offset, drift, and bias current. The AD8628/AD8629 are wide bandwidth auto-zero amplifiers featuring rail-to-rail input and output swings and low noise. Operation is fully specified from 2.7 V to 5 V single supply (± 1.35 V to ± 2.5 V dual supply).

The AD8628/AD8629 provide benefits previously found only in expensive auto-zeroing or chopper-stabilized amplifiers. Using Analog Devices' new topology, these zero-drift amplifiers combine low cost with high accuracy and low noise. (No external capacitor is required.) In addition, the AD8628/AD8629 greatly reduce the digital switching noise found in most chopper-stabilized amplifiers.

PIN CONFIGURATIONS

Figure 1. 5-Lead TSOT (UJ-5) and 5-Lead SOT-23 (RT-5)

Figure 2. 8-Lead SOIC (R-8)

Figure 3. 8-Lead SOIC (R-8)

Figure 4. 8-Lead MSOP (RM-8)

With an offset voltage of only 1 μV , drift of less than 0.005 $\mu\text{V}/^\circ\text{C}$, and noise of only 0.5 μV p-p (0 Hz to 10 Hz), the AD8628/AD8629 are perfectly suited for applications in which error sources cannot be tolerated. Position and pressure sensors, medical equipment, and strain gage amplifiers benefit greatly from nearly zero drift over their operating temperature range. Many systems can take advantage of the rail-to-rail input and output swings provided by the AD8628/AD8629 to reduce input biasing complexity and maximize SNR.

The AD8628/AD8629 are specified for the extended industrial temperature range (-40°C to $+125^\circ\text{C}$). The AD8628 is available in tiny TSOT-23, SOT-23, and the popular 8-lead narrow SOIC plastic packages. The AD8629 is available in the standard 8-lead narrow SOIC and MSOP plastic packages.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameters	Ratings
Supply Voltage	6 V
Input Voltage	GND – 0.3 V to $V_{S-} + 0.3$ V
Differential Input Voltage ¹	±5.0 V
Output Short-Circuit Duration to GND	Indefinite
Storage Temperature Range	
R, RM, RT, UJ Packages	–65°C to +150°C
Operating Temperature Range	–40°C to +125°C
Junction Temperature Range	
R, RM, RT, UJ Packages	–65°C to +150°C
Lead Temperature Range (Soldering, 60 s)	300°C

¹ Differential input voltage is limited to ±5 V or the supply voltage, whichever is less.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 4. Thermal Characteristics

Package Type	θ_{JA} ¹	θ_{JC}	Unit
5-Lead TSOT-23 (UJ-5)	207	61	°C/W
5-Lead SOT-23 (RT-5)	230	146	°C/W
8-Lead SOIC (R-8)	158	43	°C/W
8-Lead MSOP (RM-8)	190	44	°C/W

¹ θ_{JA} is specified for worst-case conditions, that is, θ_{JA} is specified for the device soldered in a circuit board for surface-mount packages.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

FUNCTIONAL DESCRIPTION

The AD8628/AD8629 are single-supply, ultrahigh precision rail-to-rail input and output operational amplifiers. The typical offset voltage of less than $1\ \mu\text{V}$ allows these amplifiers to be easily configured for high gains without risk of excessive output voltage errors. The extremely small temperature drift of $2\ \text{nV}/^\circ\text{C}$ ensures a minimum of offset voltage error over their entire temperature range of -40°C to $+125^\circ\text{C}$, making these amplifiers ideal for a variety of sensitive measurement applications in harsh operating environments.

The AD8628/AD8629 achieve a high degree of precision through a patented combination of auto-zeroing and chopping. This unique topology allows the AD8628/AD8629 to maintain their low offset voltage over a wide temperature range and over their operating lifetime. The AD8628/AD8629 also optimize the noise and bandwidth over previous generations of auto-zero amplifiers, offering the lowest voltage noise of any auto-zero amplifier by more than 50%.

Previous designs used either auto-zeroing or chopping to add precision to the specifications of an amplifier. Auto-zeroing results in low noise energy at the auto-zeroing frequency, at the expense of higher low-frequency noise due to aliasing of wideband noise into the auto-zeroed frequency band. Chopping results in lower low-frequency noise at the expense of larger noise energy at the chopping frequency. The AD8628/AD8629 family use both auto-zeroing and chopping in a patented ping-pong arrangement to obtain lower low-frequency noise together with lower energy at the chopping and auto-zeroing frequencies, maximizing the signal-to-noise ratio (SNR) for the majority of applications without the need for additional filtering. The relatively high clock frequency of $15\ \text{kHz}$ simplifies filter requirements for a wide, useful, noise-free bandwidth.

The AD8628 is among the few auto-zero amplifiers offered in the 5-lead TSOT-23 package. This provides a significant improvement over the ac parameters of the previous auto-zero amplifiers. The AD8628/AD8629 have low noise over a relatively wide bandwidth (0 Hz to $10\ \text{kHz}$) and can be used where the highest dc precision is required. In systems with signal bandwidths of from $5\ \text{kHz}$ to $10\ \text{kHz}$, the AD8628/AD8629 provide true 16-bit accuracy, making them the best choice for very high resolution systems.

1/F NOISE

$1/f$ noise, also known as pink noise, is a major contributor to errors in dc-coupled measurements. This $1/f$ noise error term can be in the range of several μV or more, and, when amplified with the closed-loop gain of the circuit, can show up as a large output offset. For example, when an amplifier with a $5\ \mu\text{V}$ p-p $1/f$ noise is configured for a gain of 1,000, its output has $5\ \text{mV}$ of error due to the $1/f$ noise. But the AD8628/AD8629 eliminate $1/f$ noise internally, and thereby greatly reduce output errors.

The internal elimination of $1/f$ noise is accomplished as follows. $1/f$ noise appears as a slowly varying offset to AD8628/AD8629 inputs. Auto-zeroing corrects any dc or low frequency offset. Therefore, the $1/f$ noise component is essentially removed, leaving the AD8628/AD8629 free of $1/f$ noise.

One of the biggest advantages that the AD8628/AD8629 bring to systems applications over competitive auto-zero amplifiers is their very low noise. The comparison shown in Figure 49 indicates an input-referred noise density of $19.4\ \text{nV}/\sqrt{\text{Hz}}$ at $1\ \text{kHz}$ for the AD8628, which is much better than the LTC2050 and LMC2001. The noise is flat from dc to $1.5\ \text{kHz}$, slowly increasing up to $20\ \text{kHz}$. The lower noise at low frequency is desirable where auto-zero amplifiers are widely used.

Figure 49. Noise Spectral Density of AD8628 vs. Competition

PEAK-TO-PEAK NOISE

Because of the ping-pong action between auto-zeroing and chopping, the peak-to-peak noise of the AD8628/AD8629 is much lower than the competition. Figure 50 and Figure 51 show this comparison.

Figure 50. AD8628 Peak-to-Peak Noise

Figure 51. LTC2050 Peak-to-Peak Noise

NOISE BEHAVIOR WITH FIRST-ORDER LOW-PASS FILTER

The AD8628 was simulated as a low-pass filter and then configured as shown in Figure 52. The behavior of the AD8628 matches the simulated data. It was verified that noise is rolled off by first-order filtering.

Figure 52. Test Circuit: First-Order Low-Pass Filter— $\times 101$ Gain and 3 kHz Corner Frequency

Figure 53. Simulation Transfer Function of the Test Circuit

Figure 54. Actual Transfer Function of Test Circuit

The measured noise spectrum of the test circuit shows that noise between 5 kHz and 45 kHz is successfully rolled off by the first-order filter.

TOTAL INTEGRATED INPUT-REFERRED NOISE FOR FIRST-ORDER FILTER

For a first-order filter, the total integrated noise from the AD8628 is lower than the LTC2050.

Figure 55. 3 dB Filter Bandwidth in Hz

INPUT OVERVOLTAGE PROTECTION

Although the AD8628/AD8629 are rail-to-rail input amplifiers, care should be taken to ensure that the potential difference between the inputs does not exceed the supply voltage. Under normal negative feedback operating conditions, the amplifier corrects its output to ensure that the two inputs are at the same voltage. However, if either input exceeds either supply rail by more than 0.3 V, large currents begin to flow through the ESD protection diodes in the amplifier.

These diodes are connected between the inputs and each supply rail to protect the input transistors against an electrostatic discharge event and are normally reverse-biased. However, if the input voltage exceeds the supply voltage, these ESD diodes can become forward-biased. Without current limiting, excessive amounts of current could flow through these diodes, causing permanent damage to the device. If inputs are subject to overvoltage, appropriate series resistors should be inserted to limit the diode current to less than 5 mA maximum.

OUTPUT PHASE REVERSAL

Output phase reversal occurs in some amplifiers when the input common-mode voltage range is exceeded. As common-mode voltage is moved outside of the common-mode range, the outputs of these amplifiers can suddenly jump in the opposite direction to the supply rail. This is the result of the differential input pair shutting down, causing a radical shifting of internal voltages that results in the erratic output behavior.

The AD8628/AD8629 amplifiers have been carefully designed to prevent any output phase reversal, provided that both inputs are maintained within the supply voltages. If one or both inputs could exceed either supply voltage, a resistor should be placed in series with the input to limit the current to less than 5 mA. This ensures that the output does not reverse its phase.

OVERLOAD RECOVERY TIME

Many auto-zero amplifiers are plagued by a long overload recovery time, often in ms, due to the complicated settling behavior of the internal nulling loops after saturation of the outputs. The AD8628/AD8629 have been designed so that internal settling occurs within two clock cycles after output saturation happens. This results in a much shorter recovery time, less than 10 μ s, when compared to other auto-zero amplifiers. The wide bandwidth of the AD8628/AD8629 enhances performance when they are used to drive loads that inject transients into the outputs. This is a common situation when an amplifier is used to drive the input of switched capacitor ADCs.

Figure 56. Positive Input Overload Recovery for the AD8628

Figure 59. Negative Input Overload Recovery for the AD8628

Figure 60. Negative Input Overload Recovery for LTC2050

Figure 61. Negative Input Overload Recovery for LMC2001

The results shown in Figure 56 to Figure 61 are summarized in Table 5.

Table 5. Overload Recovery Time

Product	Positive Overload Recovery (μ s)	Negative Overload Recovery (μ s)
AD8628	6	9
LTC2050	650	25,000
LMC2001	40,000	35,000

INFRARED SENSORS

Infrared (IR) sensors, particularly thermopiles, are increasingly being used in temperature measurement for applications as wide-ranging as automotive climate control, human ear thermometers, home insulation analysis, and automotive repair diagnostics. The relatively small output signal of the sensor demands high gain with very low offset voltage and drift to avoid dc errors.

If interstage ac coupling is used (Figure 62), low offset and drift prevents the input amplifier's output from drifting close to saturation. The low input bias currents generate minimal errors from the sensor's output impedance. As with pressure sensors, the very low amplifier drift with time and temperature eliminates additional errors once the temperature measurement has been calibrated. The low 1/f noise improves SNR for dc measurements taken over periods often exceeding 1/5 s.

Figure 64 (shows a circuit that can amplify ac signals from 100 μ V to 300 μ V up to the 1 V to 3 V level, with gain of 10,000 for accurate A/D conversion.

Figure 62. AD8629 Used as Preamplifier for Thermopile

PRECISION CURRENT SHUNTS

A precision shunt current sensor benefits from the unique attributes of auto-zero amplifiers when used in a differencing configuration (Figure 63). Shunt current sensors are used in precision current sources for feedback control systems. They are also used in a variety of other applications, including battery fuel gauging, laser diode power measurement and control, torque feedback controls in electric power steering, and precision power metering.

Figure 63. Low-Side Current Sensing

In such applications, it is desirable to use a shunt with very low resistance to minimize the series voltage drop; this minimizes wasted power and allows the measurement of high currents without saving power. A typical shunt might be 0.1 Ω . At measured current values of 1 A, the shunt's output signal is hundreds of mV, or even V, and amplifier error sources are not critical. However, at low measured current values in the 1 mA range, the 100 μ V output voltage of the shunt demands a very low offset voltage and drift to maintain absolute accuracy. Low input bias currents are also needed, so that injected bias current does not become a significant percentage of the measured current. High open-loop gain, CMRR, and PSRR all help to maintain the overall circuit accuracy. As long as the rate of change of the current is not too fast, an auto-zero amplifier can be used with excellent results.

OUTPUT AMPLIFIER FOR HIGH PRECISION DACs

The AD8628/AD8629 are used as output amplifiers for a 16-bit high precision DAC in a unipolar configuration. In this case, the selected op amp needs to have very low offset voltage (the DAC LSB is 38 μ V when operated with a 2.5 V reference) to eliminate the need for output offset trims. Input bias current (typically a few tens of picoamperes) must also be very low, because it generates an additional zero code error when multiplied by the DAC output impedance (approximately 6 k Ω).

Rail-to-rail input and output provide full-scale output with very little error. Output impedance of the DAC is constant and code-independent, but the high input impedance of the AD8628/AD8629 minimizes gain errors. The amplifiers' wide bandwidth also serves well in this case. The amplifiers, with settling time of 1 μ s, add another time constant to the system, increasing the settling time of the output. The settling time of the AD5541 is 1 μ s. The combined settling time is approximately 1.4 μ s, as can be derived from the following equation:

$$t_S (TOTAL) = \sqrt{(t_S DAC)^2 + (t_S AD8628)^2}$$
