

Dual, 4.5MHz, BiMOS Operational Amplifier with MOSFET Input/Bipolar Output

The CA3240A and CA3240 are dual versions of the popular CA3140 series integrated circuit operational amplifiers. They combine the advantages of MOS and bipolar transistors on the same monolithic chip. The gate-protected MOSFET (PMOS) input transistors provide high input impedance and a wide common-mode input voltage range (typically to 0.5V below the negative supply rail). The bipolar output transistors allow a wide output voltage swing and provide a high output current capability.

The CA3240A and CA3240 are compatible with the industry standard 1458 operational amplifiers in similar packages. The offset null feature is available only when these types are supplied in the 14 lead PDIP package (E1 suffix).

Ordering Information

PART NUMBER	TEMP. RANGE (°C)	PACKAGE	PKG. NO.
CA3240AE	-40 to 85	8 Ld PDIP	E8.3
CA3240AE1	-40 to 85	14 Ld PDIP	E14.3
CA3240E	-40 to 85	8 Ld PDIP	E8.3

Functional Diagram

NOTE: Only available with 14 lead DIP (E1 Suffix).

Features

- Dual Version of CA3140
- Internally Compensated
- MOSFET Input Stage
 - Very High Input Impedance (Z_{IN}) 1.5TΩ (Typ)
 - Very Low Input Current (I_I) 10pA (Typ) at ±15V
 - Wide Common-Mode Input Voltage Range (V_{ICR}): Can Be Swung 0.5V Below Negative Supply Voltage Rail
- Directly Replaces Industry Type 741 in Most Applications

Applications

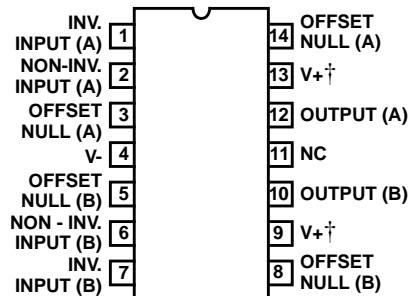

- Ground Referenced Single Amplifiers in Automobile and Portable Instrumentation
- Sample and Hold Amplifiers
- Long Duration Timers/Multivibrators (Microseconds-Minutes-Hours)
- Photocurrent Instrumentation
- Intrusion Alarm System
- Comparators
- Instrumentation Amplifiers
- Active Filters
- Function Generators
- Power Supplies

Absolute Maximum Ratings

Supply Voltage (Between V+ and V-)	36V
Differential Input Voltage	8V
Input Voltage	(V+ +8V) to (V- -0.5V)
Input Current	1mA
Output Short Circuit Duration (Note 1)	Indefinite

Thermal Information

Thermal Resistance (Typical, Note 2)	θ_{JA} (°C/W)
8 Lead PDIP Package	100
14 Lead PDIP Package	100
Maximum Junction Temperature (Plastic Package)	150°C
Maximum Storage Temperature Range	-65°C to 150°C
Maximum Lead Temperature (Soldering 10s)	300°C

Operating Conditions

Temperature Range	-40°C to 85°C
Voltage Range	4V to 36V or ±2V to ±18V

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

NOTES:

- Short circuit may be applied to ground or to either supply. Temperatures and/or supply voltages must be limited to keep dissipation within maximum rating.
- θ_{JA} is measured with the component mounted on an evaluation PC board in free air.

Application Information

Circuit Description

The schematic diagram details one amplifier section of the CA3240. It consists of a differential amplifier stage using PMOS transistors (Q_9 and Q_{10}) with gate-to-source protection against static discharge damage provided by zener diodes D_3 , D_4 , and D_5 . Constant current bias is applied to the differential amplifier from transistors Q_2 and Q_5 connected as a constant current source. This assures a high common-mode rejection ratio. The output of the differential amplifier is coupled to the base of gain stage transistor Q_{13} by means of an NPN current mirror that supplies the required differential-to-single-ended conversion. Provision for offset null for types in the 14 lead plastic package (E1 suffix) is provided through the use of this current mirror.

The gain stage transistor Q_{13} has a high impedance active load (Q_3 and Q_4) to provide maximum open-loop gain. The collector of Q_{13} directly drives the base of the compound emitter-follower output stage. Pull-down for the output stage is provided by two independent circuits: (1) constant-current-connected transistors Q_{14} and Q_{15} and (2) dynamic current-sink transistor Q_{16} and its associated circuitry. *The level of pull-down current is constant at about 1mA for Q_{15} and varies from 0 to 18mA for Q_{16} depending on the magnitude of the voltage between the output terminal and V_+ .* The dynamic current sink becomes active whenever the output terminal is more negative than V_+ by about 15V. When this condition exists, transistors Q_{21} and Q_{16} are turned on causing Q_{16} to sink current from the output terminal to V_- . This current always flows when the output is in the linear region, either from the load resistor or from the emitter of Q_{18} if no load resistor is present. The purpose of this dynamic sink is to permit the output to go within 0.2V ($V_{CE(sat)}$) of V_- with a 2k Ω load to ground. *When the load is returned to V_+ , it may be necessary to supplement the 1mA of current from Q_{15} in order to turn on the dynamic current sink (Q_{16}).* This may be accomplished by placing a resistor (Approx. 2k Ω) between the output and V_- .

Output Circuit Considerations

Figure 24 shows output current-sinking capabilities of the CA3240 at various supply voltages. Output voltage swing to the negative supply rail permits this device to operate both power transistors and thyristors directly without the need for level-shifting circuitry usually associated with the 741 series of operational amplifiers.

Figure 3 shows some typical configurations. Note that a series resistor, R_L , is used in both cases to limit the drive available to the driven device. Moreover, it is recommended that a series diode and shunt diode be used at the thyristor input to prevent large negative transient surges that can appear at the gate of thyristors, from damaging the integrated circuit.

Input Circuit Considerations

As indicated by the typical VICR, this device will accept inputs as low as 0.5V below V_- . However, a series current-limiting resistor is recommended to limit the maximum input terminal current to less than 1mA to prevent damage to the input protection circuitry.

Moreover, some current-limiting resistance should be provided between the inverting input and the output when the CA3240 is used as a unity-gain voltage follower. This resistance prevents the possibility of extremely large input-signal transients from forcing a signal through the input-protection network and directly driving the internal constant-current source which could result in positive feedback via the output terminal. A 3.9k Ω resistor is sufficient.

The typical input current is on the order of 10pA when the inputs are centered at nominal device dissipation. As the output supplies load current, device dissipation will increase, raising the chip temperature and resulting in increased input current. Figure 4 shows typical input-terminal current versus ambient temperature for the CA3240.

FIGURE 3. METHODS OF UTILIZING THE $V_{CE(sat)}$ SINKING CURRENT CAPABILITY OF THE CA3240 SERIES

FIGURE 4. INPUT CURRENT vs TEMPERATURE

It is well known that MOSFET devices can exhibit slight changes in characteristics (for example, small changes in input offset voltage) due to the application of large differential input voltages that are sustained over long periods at elevated temperatures.

Both applied voltage and temperature accelerate these changes. The process is reversible and offset voltage shifts of the opposite polarity reverse the offset. In typical linear applications, where the differential voltage is small and symmetrical, these incremental changes are of about the same magnitude as those encountered in an operational amplifier employing a bipolar transistor input stage.

Offset-Voltage Nulling

The input offset voltage of the CA3240AE1 and CA3240E1 can be nulled by connecting a 10k Ω potentiometer between Terminals 3 and 14 or 5 and 8 and returning its wiper arm to Terminal 4, see Figure 5A. This technique, however, gives more adjustment range than required and therefore, a considerable portion of the potentiometer rotation is not fully utilized. Typical values of series resistors that may be placed at either end of the potentiometer, see Figure 5B, to optimize its utilization range are given in the table "Electrical Specifications for Equipment Design" shown on third page of this data sheet. An alternate system is shown in Figure 5C. This circuit uses only one additional resistor of approximately the value shown in the table. For potentiometers, in which the resistance does not drop to 0 Ω at either end of rotation, a value of resistance 10% lower than the values shown in the table should be used.

Typical Applications

On/Off Touch Switch

The on/off touch switch shown in Figure 6 uses the CA3240E to sense small currents flowing between two contact points on a touch plate consisting of a PC board metallization "grid". When the "on" plate is touched, current flows between the two halves of the grid causing a positive

shift in the output voltage (Terminal 7) of the CA3240E. These positive transitions are fed into the CA3059, which is used as a latching circuit and zero-crossing TRIAC driver. When a positive pulse occurs at Terminal 7 of the CA3240E, the TRIAC is turned on and held on by the CA3059 and its associated positive feedback circuitry (51k Ω resistor and 36k Ω /42k Ω voltage divider). When the positive pulse occurs at Terminal 1 (CA3240E), the TRIAC is turned off and held off in a similar manner. Note that power for the CA3240E is supplied by the CA3059 internal power supply.

The advantage of using the CA3240E in this circuit is that it can sense the small currents associated with skin conduction while allowing sufficiently high circuit impedance to provide protection against electrical shock.

Dual Level Detector (Window Comparator)

Figure 7 illustrates a simple dual liquid level detector using the CA3240E as the sensing amplifier. This circuit operates on the principle that most liquids contain enough ions in solution to sustain a small amount of current flow between two electrodes submerged in the liquid. The current, induced by an 0.5V potential applied between two halves of a PC board grid, is converted to a voltage level by the CA3240E in a circuit similar to that of the on/off touch switch shown in Figure 6. The changes in voltage for both the upper and lower level sensors are processed by the CA3140 to activate an LED whenever the liquid level is above the upper sensor or below the lower sensor.

Constant-Voltage/Constant-Current Power Supply

The constant-voltage/constant-current power supply shown in Figure 8 uses the CA3240E1 as a voltage-error and current-sensing amplifier. The CA3240E1 is ideal for this application because its input common-mode voltage range includes ground, allowing the supply to adjust from 20mV to 25V without requiring a negative supply voltage. Also, the ground reference capability of the CA3240E1 allows it to sense the voltage across the 1 Ω current-sensing resistor in the negative output lead of the power supply. The CA3086 transistor array functions as a reference for both constant-voltage and constant-current limiting. The 2N6385 power Darlington is used as the pass element and may be required to dissipate as much as 40W. Figure 9 shows the transient response of the supply during a 100mA to 1A load transition.

Precision Differential Amplifier

Figure 10 shows the CA3240E in the classical precision differential amplifier circuit. The CA3240E is ideally suited for biomedical applications because of its extremely high input impedance. To insure patient safety, an extremely high electrode series resistance is required to limit any current that might result in patient discomfort in the event of a fault condition. In this case, 10M Ω resistors have been used to limit the current to less than 2 μ A without affecting the performance of the circuit. Figure 11 shows a typical electrocardiogram waveform obtained with this circuit.

FIGURE 12. DIFFERENTIAL LIGHT DETECTOR

Differential Light Detector

In the circuit shown in Figure 12, the CA3240E converts the current from two photo diodes to voltage, and applies 1V of reverse bias to the diodes. The voltages from the CA3240E outputs are subtracted in the second stage (CA3140) so that

only the difference is amplified. In this manner, the circuit can be used over a wide range of ambient light conditions without circuit component adjustment. Also, when used with a light source, the circuit will not be sensitive to changes in light level as the source ages.
