

CCB LC72121MA

CMOS IC

PLL Frequency Synthesizers for Electronic Tuning

ON Semiconductor®

<http://onsemi.com>

Overview

The LC72121MA are high input sensitivity (20mVrms at 130MHz) PLL frequency synthesizers for 3V systems. These ICs are serial data (CCB) compatible with the LC72131K/KMA, and feature the improved input sensitivity and lower spurious radiation (provided by a redesigned ground system) required in high-performance AM/FM tuners.

Features

- High-speed programmable divider
 - FMIN: 10 to 160MHz Pulse swallower technique (With built-in divide-by-2 prescaler)
 - AMIN: 2 to 40MHz Pulse swallower technique
 - 0.5 to 10MHz Direct division technique
- IF counter
 - IFIN: 0.4 to 15MHz For AM and FM IF counting
- Reference frequency
 - One of 12 reference frequencies can be selected (using a 4.5 or 7.2MHz crystal element)
 - 1, 3, 5, 9, 10, 3.125, 6.25, 12.5, 15, 25, 50, and 100kHz
- Phase comparator
 - Supports dead zone control. • Built-in unlocked state detection circuit • Built-in deadlock clear circuit
 - An MOS transistor for an active low-pass filter is built in.
- I/O ports
 - Output-only ports: 4 pins • I/O ports: 2 pins • Supports the output of a clock time base signal.
- Serial data I/O
 - Support CCB format communication with the system controller.
- Operating ranges
 - Supply voltage: 2.7 to 3.6V • Operating temperature: -40 to +85°C
- Package
 - MFP24SJ

• CCB is ON Semiconductor®'s original format. All addresses are managed by ON Semiconductor® for this format.

- CCB is a registered trademark of Semiconductor Components Industries, LLC.

LC72121MA

Specifications

Absolute Maximum Ratings at $T_a = 25^\circ\text{C}$, $V_{SSd} = V_{SSa} = V_{SSX} = 0\text{V}$

Parameter	Symbol	Conditions	Ratings	Unit
Maximum supply voltage	V_{DD} max	V_{DD}	-0.3 to +7.0	V
Maximum input voltage	V_{IN1} max	CE, CL, DI, AIN	-0.3 to +7.0	V
	V_{IN2} max	XIN, FMIN, AMIN, IFIN	-0.3 to $V_{DD}+0.3$	V
	V_{IN3} max	$\overline{IO1}$, $\overline{IO2}$	-0.3 to +15	V
Maximum output voltage	V_{O1} max	DO	-0.3 to +7.0	V
	V_{O2} max	XOUT, PD	-0.3 to $V_{DD}+0.3$	V
	V_{O3} max	$\overline{BO1}$ to $\overline{BO4}$, $\overline{IO1}$, $\overline{IO2}$, AOUT	-0.3 to +15	V
Maximum output current	I_{O1} max	DO, AOUT	0 to 6.0	mA
	I_{O2} max	$\overline{BO1}$ to $\overline{BO4}$, $\overline{IO1}$, $\overline{IO2}$	0 to 10	mA
Allowable power dissipation	P_d max	($T_a \leq 85^\circ\text{C}$)	200	mW
Operating temperature	T_{opr}		-40 to +85	$^\circ\text{C}$
Storage temperature	T_{stg}		-55 to +125	$^\circ\text{C}$

Note 1: Power pins V_{DD} and V_{SS} : Insert a capacitor with a capacitance of 2,000pF or higher between these pins when using the IC.

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

Allowable Operating Ranges at $T_a = -40$ to $+85^\circ\text{C}$, $V_{SSd} = V_{SSa} = V_{SSX} = 0\text{V}$

Parameter	Symbol	Pin	Conditions	Ratings			Unit
				min	typ	max	
Supply voltage	V_{DD}	V_{DD}		2.7		3.6	V
Input high-level voltage	V_{IH1}	CE, CL, DI		$0.7V_{DD}$		6.5	V

LC72121MA

Note 2: Recommended crystal oscillator CI values:

$CI \leq 120\Omega$ (For a 4.5MHz crystal)

$CI \leq 70\Omega$ (For a 7.2MHz crystal)

The characteristics of the oscillation circuit depends on the printed circuit board, circuit constants, and other factors. Therefore we recommend consulting with the manufacturer of the crystal for evaluation and reliability.

Note 3: Refer to "Serial Data Timing".

LC72121MA

Structure of the IF Counter

The LC72121MA IF counter is a 20-bit binary counter, and takes the IF signal from the IFIN pin as its input. The result of the count can be read out serially, MSB first, from the DO pin.

GT1	GT0	Measurement time	
		Measurement time (GT)	Wait time (t _{WU})
0	0	4 ms	3 to 4 ms
0	1	8	3 to 4
1	0	32	7 to 8
1	1	64	7 to 8

The IF frequency (Fc) is measured by determining how many pulses were input to the IF counter in the stipulated measurement time, GT.

$$F_c = \frac{C}{GT} \quad (C = F_c \times GT) \quad C: \text{Counted value (the number of pulses)}$$

IF Counter Frequency Measurement Examples

- (1) When the measurement time (GT) is 32ms and the counted value (C) is 53980 (hexadecimal) or 342,400 (decimal).

$$\text{IF frequency (Fc)} = 342400 \div 32\text{ms} = 10.7\text{MHz}$$

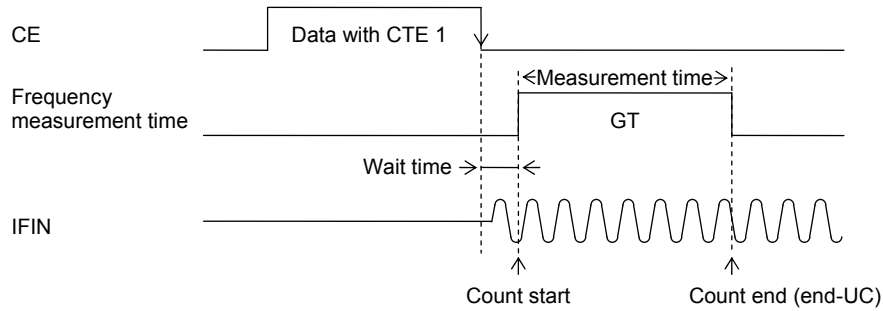

- (2) When the measurement time (GT) is 8ms and the counted value (C) is E10 (hexadecimal) or 3600 (decimal).

$$\text{IF frequency (FC)} = 3600 \div 8\text{ms} = 450\text{kHz}$$

IF Counter Operation

Applications must first, before starting an IF count operation reset the IF counter by setting CTE in the serial data to 0. The IF counter operation is started setting CTE in the serial data from 0 to 1. Although the serial data is latched by dropping the CE pin from high to low, the IF signal input to the IFIN pin must be provided within the wait time from the point CE goes low. Next, the readout of the IF counter after measurement is complete must be performed while CTE is still 1, since the counter will be reset if CTE is set to 0.

Note: If IF counting is used, applications must determine whether or not the IF IC SD (station detect) signal is present in the microcontroller software, and perform the IF count only if that signal is asserted. This is because auto-search techniques that use IF counting only are subject to incorrect stopping at points where there is no station due to IF buffer leakage.

Note that the LC72121MA input sensitivity can be controlled with the IFS bit in the serial data. Reduced sensitivity mode (IFS = 0) must be selected when this IC is used in conjunction with an IF IC that does not provide an SD output and auto-search is implemented using only IF counting.

IFIN Minimum Sensitivity Standard

IFS data	Input frequency : f [MHz]		
	$0.4 \leq f < 0.5$	$0.5 \leq f < 8$	$8 \leq f \leq 15$
1 (Normal mode)	40mVrms (0.1 to 3mVrms)	40mVrms	40mVrms(1 to 15mVrms)
0 (Degraded sensitivity mode)	70mVrms(5 to 10mVrms)	70mVrms	70mVrms(30 to 40mVrms)

Note: Values in parentheses are actual performance values that are provided for reference purposes.

Unlocked State Detection

1. Unlocked state detection timing

Unlocked state detection is performed during the reference frequency (f_{ref}) period (interval). This means that a period at least as long as the period of the reference frequency is required to recognize the locked/unlocked state. However, applications must wait at least twice the period of the reference frequency immediately after changing the divisor (N) before checking the locked/unlocked state.

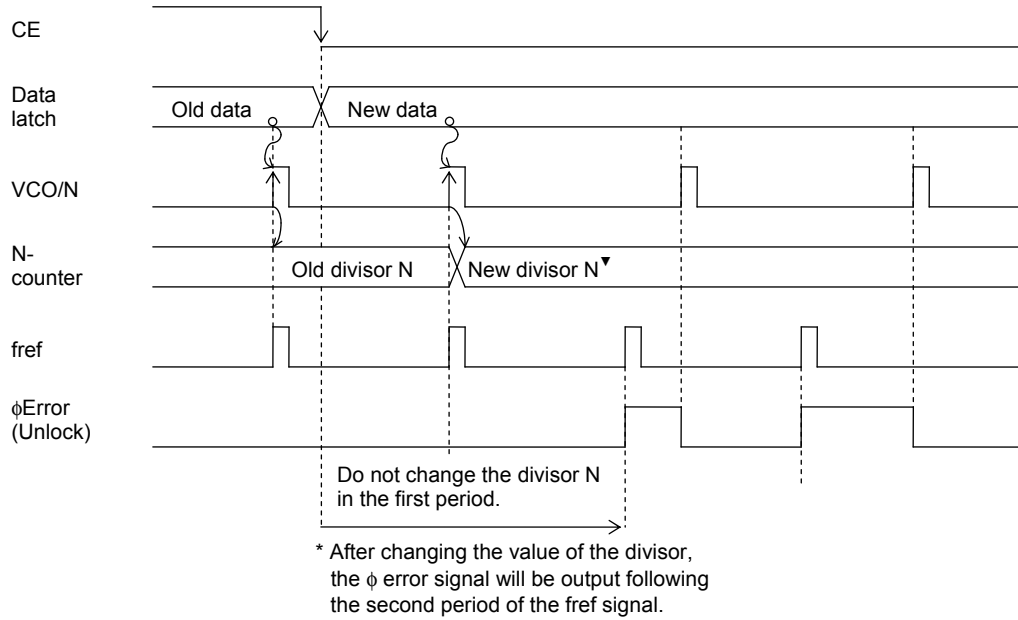

Figure 1 Unlocked State Detection Timing

For example, if f_{ref} is 1kHz (a period of 1ms) applications must wait at least 2 ms after the divisor N is changed before performing a locked/unlocked check.

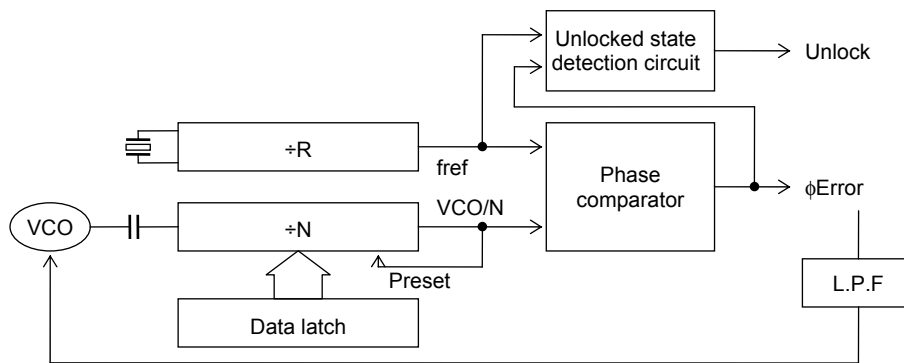

Figure 2 Circuit Structure

2. Combining with Software

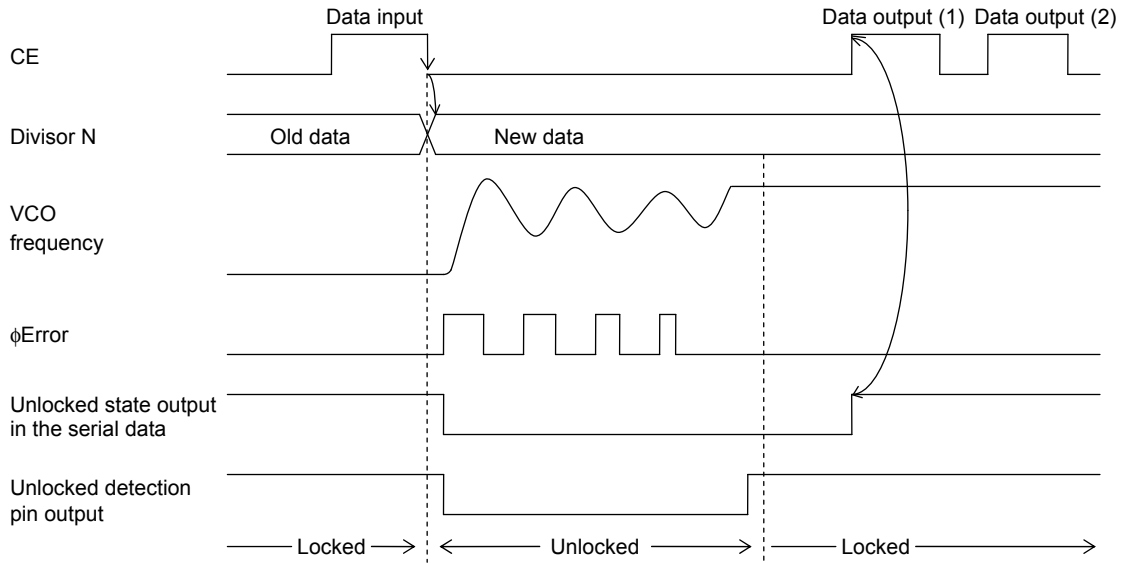

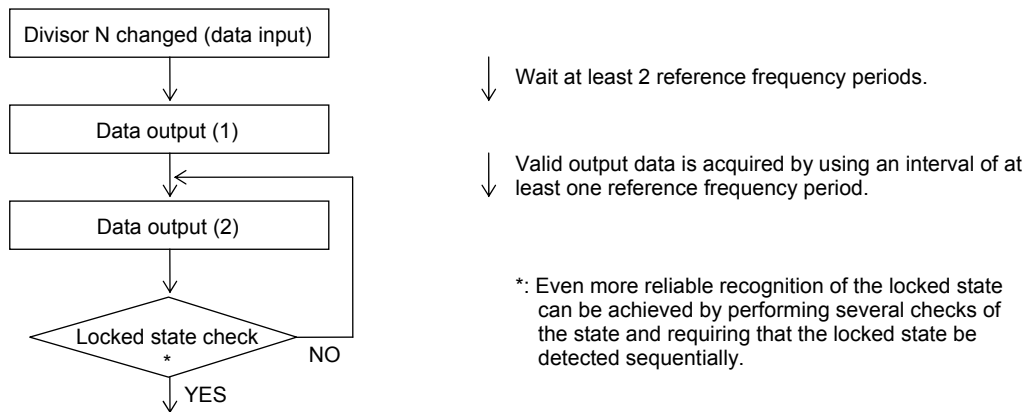

Figure 3 Combining with Software

3. Outputting the unlocked state data in the serial data

At the point of data output 1 in figure 3, the unlocked state data will indicate the unlocked state, since the VCO frequency is not stable (locked) yet. In cases such as this, the application should wait at least one whole period and then check again whether or not the frequency has stabilized with the data output 2 operation in the figure. Applications can implement even more reliable recognition of the locked state by performing several more checks of the state and requiring that the locked state be detected sequentially.

<Flowchart for Lock Detection>

4. Directly outputting the unlocked state to the DO pin

Since the unlocked state (high level when locked, low when unlocked) is output from the DO pin, applications can check for the locked state by waiting at least two reference frequency periods after changing the divisor N. However, in this case also, even more reliable recognition of the locked state can be achieved by performing several checks of the state and requiring that the locked state be detected sequentially.

LC72121MA

Clock Time Base Usage Notes

When using the clock time base output function, the output pin ($\overline{\text{BO1}}$) pull-up resistor must have a value of over $100\text{k}\Omega$. The use of a Schmitt input in the microcontroller that accepts this signal is recommended to reduce chattering. This is to prevent degradation of the VCO C/N characteristics when combining with a loop filter that uses the internal transistor provided to form a low-pass filter. Although the ground for the clock time base output pin (V_{SSd}) and the ground for the transistor (V_{SSa}) are isolated internally on the chip, applications must take care to avoid ground loops and minimize current fluctuations in the time base pin to prevent degradation of the low-pass filter characteristics.

Other Items

(1) Notes on the phase comparator dead zone

DZ1	DZ0	Dead zone mode	Charge pump	Dead zone
0	0	DZA	ON/ON	--0s
0	1	DZB	ON/ON	-0s
1	0	DZC	OFF/OFF	+0s
1	1	DZD	OFF/OFF	++0s

When the charge pump is used with one of the ON/ON modes, correction pulses are generated from the charge pump even if the PLL is locked. As a result, it is easy for the loop to become unstable, and special care is required in application design. The following problems can occur if an ON/ON mode is used.

- (1) Sidebands may be created by reference frequency leakage.
- (2) Sidebands may be created by low-frequency leakage due to the correction pulse envelope.

Although the loop is more stable when a dead zone is present (i.e. when an OFF/OFF mode is used), a dead zone makes it more difficult to achieve excellent C/N characteristics. On the other hand, while it is easy to achieve good C/N characteristics when there is no dead zone, achieving good loop stability is difficult. Accordingly, the DZA and DZB settings, in which there is no dead zone, can be effective in situations where a signal-to-noise ratio of 90 to 100dB or higher is required in FM reception, or where it is desirable to increase the pilot margin in AM stereo reception.

However, if such a high signal-to-noise ratio is not required for FM reception, if an adequate pilot margin can be acquired in AM stereo reception, or if AM stereo is not required, then either DZC or DZD, in which there is a dead zone, should be chosen.

Dead Zone

As shown in figure 1, the phase comparator compares a reference frequency (f_r) with f_p . As shown in figure 2, the phase comparator's characteristics consist of an output voltage (V) that is proportional to the phase difference ϕ . However, due to internal circuit delay and other factors, an actual circuit has a region (the dead zone, B) where the circuit cannot actually compare the phases. To implement a receiver with a high S/N ratio, it is desirable that this region be as small as possible. However, it is often desirable to have the dead zone be slightly wider in popularly-priced models. This is because in certain cases, such as when there is a strong RF input, popularly-priced models can suffer from mixer to VCO RF leakage that modulates the VCO. When the dead zone is small, the circuit outputs signals to correct this modulation and this output further modulates the VCO. This further modulation may then generate beats and the RF signal.

Figure 1

Figure 2

(2) Notes on the FMIN, AMIN, and IFIN pins

Coupling capacitors should be placed as close to their pin as possible. A capacitance of about 100pF is desirable for these capacitors. In particular, if the IFIN pin coupling capacitor is not held under 1000pF, the time to reach the bias level may become excessive and incorrect counts may result due to the relationship with the wait time.

(3) Notes on IF counting → Use the SD signal in conjunction with IF counting

When counting the IF frequency, the microcontroller must determine the presence or absence of the IF IC SD (station detect) signal and turn on the IF counter buffer output and execute the IF count only if there is an SD signal. Autosearch techniques that only use the IF counter are subject to incorrect stopping at points where there is no station due to IF buffer leakage.

(4) DO pin usage

The DO pin can be used for IF counter count completion checking and as an unlock detection output in addition to its use in data output mode. It is also possible to have the DO pin reflect the state of an input pin to input that state to the microcontroller.

(5) Power supply pins

Capacitors must be inserted between the power supply V_{DD} and V_{SS} pins for noise exclusion. These capacitors must be placed as close as possible to the V_{DD} and V_{SS} pins.

(6) VCO setup

Applications must be designed so that the VCO (local oscillator) does not stop, even if the control voltage (V_{tune}) goes to 0V. If it is possible for the oscillator to stop, the application must use the control data (DLC) to temporarily force V_{tune} to V_{CC} to prevent deadlock from occurring. (Deadlock clear circuit)

LC72121MA

(7) Front end connection example

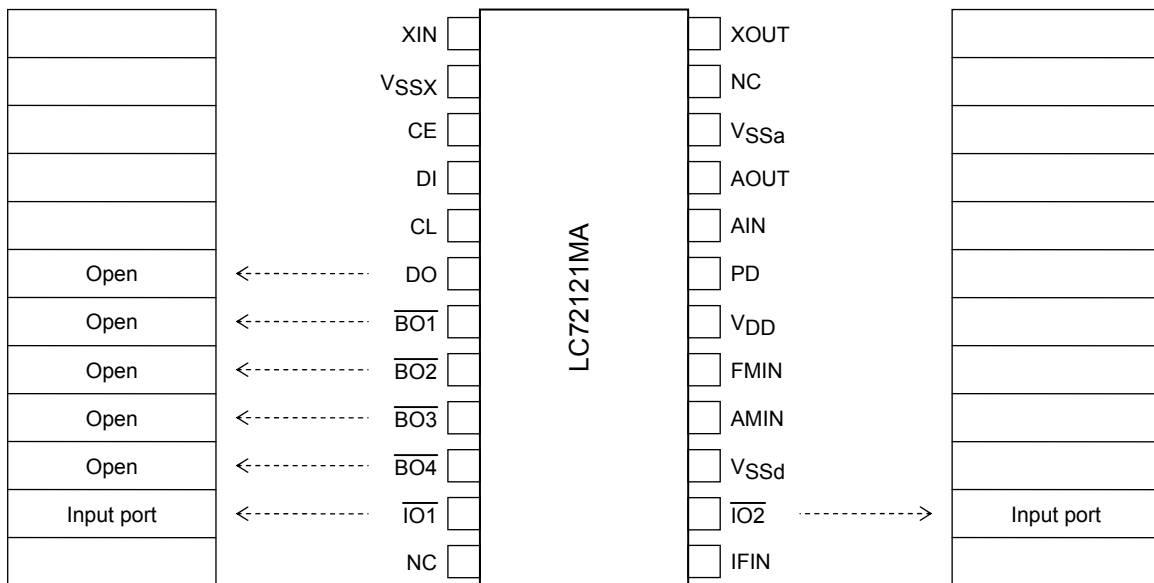

Since this product is designed with the relatively high resistance of 200kΩ for the pulldown (on) resistors built in to the FMIN and AMIN pins, a common AM/FM local oscillator buffer can be used as shown in the following circuit.

(8) PD pin

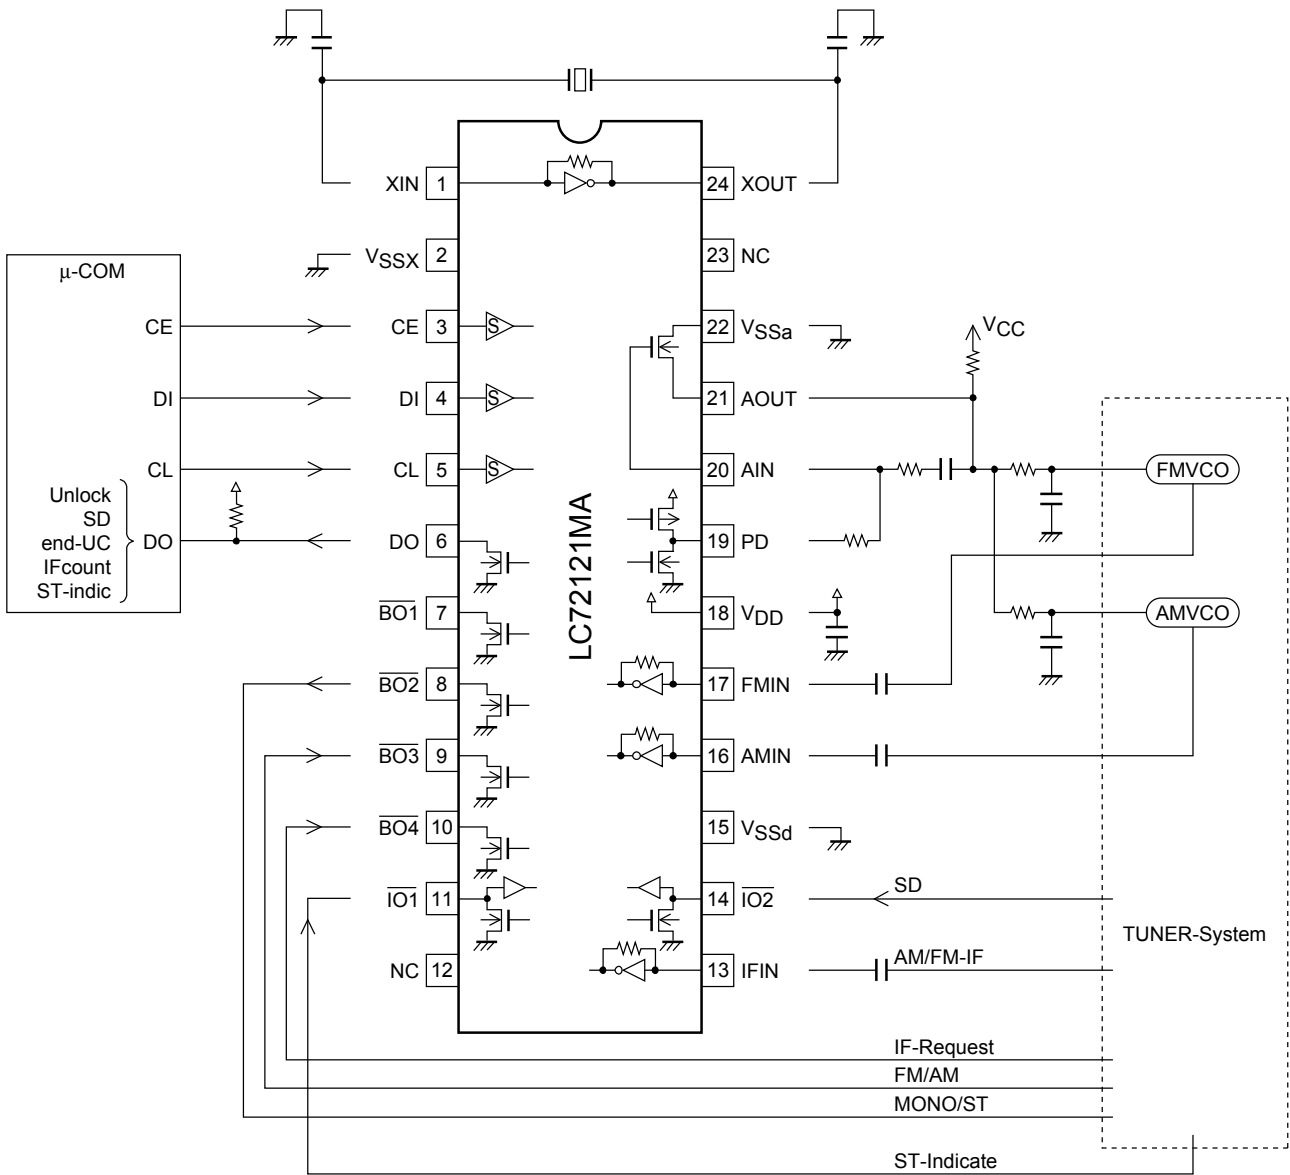

Note that the charge pump output voltage is reduced when this IC, which is a 3-V system, is used to replace the LC72131K/KMA, which is a 5-V system. This means that since the loop gain is reduced, the loop filter constants, the lock time (SD wait time), and other related parameters must be reevaluated in the end product design.

Pin States after a Power on Reset
